

Modern smartphone users frequently rely on autocorrect systems to improve typing speed and reduce spelling errors. However, these systems often incorrectly modify words that are already correct, particularly in cases involving acronyms, proper nouns, slang, or domain-specific terminology. This leads to unintended word substitutions that can distort the original meaning of messages, cause confusion in communication, and require additional time for users to review and correct errors.

The issue is especially problematic in contexts where accuracy is critical, such as professional communication, technical discussions, or messaging that includes specialized vocabulary. Existing autocorrect systems typically lack sufficient contextual awareness or personalization, resulting in repetitive correction errors and user frustration. As a result, users may disable autocorrect entirely or spend extra effort correcting automated changes, reducing overall typing efficiency and user experience.
